

The Abelianized Rung and the T_k Classification

The two remaining links of the last volume, discharged. The abelianized rung reduces exactly to commutative Hankels conjugated by the square-rooted multinomial coefficients, and the transport fails off the axes by the closed-form ratio $\rho(\gamma) = \sqrt{\mu(\gamma)}$. Beyond T_0 the Hankel-preserving conditions collapse into one monoid homomorphism, and the isometry rigidifies the class to the multiplicative gradings on the weight sphere. The sandwich is measured honestly — closed, open, and strictly failed — by the multinomial budget.
